1 Introduction

CVXR is an R package that provides an object-oriented modeling language for convex optimization, including the Second-Order Cone Optimization(SOCopt) required to minimize Expected Quadratic Shortfall(EQS) problem, which is not supported by other solvers in PortfolioAnalytics. Hence, CVXR is a great extension of PortfolioAnalytics.

The purpose of this vignette is to demonstrate examples of optimization problems that can be solved in PortfolioAnalytics with CVXR and its many supported solvers. The problem types covered include not only Linear Programming(LP), Quadratic Programming(QP) but also Second-Order Cone Programming(SOCP). Multiple solvers supported by CVXR can be selected according to optimization types. For example, SCS and ECOS can completely cover the types of problems that ROI can deal with, such as mean-variance and ES problem. In order to better understand the functions of PortfolioAnalytics, users are recommended to read the Vignette Introduction to PortfolioAnalytics first.

2 Getting Started

2.1 Load Packages

Load the necessary packages.

library(PortfolioAnalytics)
library(CVXR)
library(data.table)
library(xts)
library(PCRA)

2.2 Solvers

The website https://cvxr.rbind.io/ shows that CVXR currently supports us to use 9 solvers, some of which are commercial (CBC, CPLEX, GUROBI, MOSEK) and the others are open source(GLPK, GLPK_MI, OSQP, SCS, ECOS).

Different solvers support different types of portfolio optimization problems. The optimize_method=c("CVXR", {CVXRsolver}) argument of the function optimize.portfolio allows the user to specify the solver to use with CVXR. If the argument is optimize_method="CVXR", the default solver for LP and QP type portfolio optimization problems such as maximum mean return and minimum variance portfolio optimization, will be OSQP, and the default solver for SOCP type portfolio optimizations, such as "robust portfolio optimization" to control for alpha uncertainty, and Expected Quadratic Shortfall (EQS) portfolio optimization, will be SCS.

Solver	$_{ m LP}$	QP	SOCP
CBC	√		
GLPK	\checkmark		
$GLPK_MI$	\checkmark		
OSQP	✓	√	
SCS	$\overline{\checkmark}$	$\overline{\checkmark}$	\checkmark
ECOS	\checkmark	\checkmark	$\overline{\checkmark}$
CPLEX	\checkmark	\checkmark	\checkmark
GUROBI	\checkmark	\checkmark	\checkmark

Solver	LP	QP	SOCP
MOSEK	✓	✓	✓

2.3 Data

The edhec data set from the PerformanceAnalytics package is used as example data for examples from Section 3 to Section 8. The edhec data contains monthly returns for 13 assets from 1997-01 to 2019-11. We use the edhec data of the last 5 years as the example data to mainly show how to use the code.

```
data(edhec)
# Use edhec for a returns object
ret_edhec <- tail(edhec, 60)</pre>
colnames(ret_edhec) <- c("CA", "CTAG", "DS", "EM", "EMN", "ED", "FIA",
                       "GM", "LSE", "MA", "RV", "SS", "FF")
print(head(ret_edhec, 5))
##
                   CA
                         CTAG
                                   DS
                                           EM
                                                  EMN
                                                           ED
                                                                   FIA
                                                                            GM

tsPlotMP is a function of R package PCRA which can plot time series for the return data.

```
tsPlotMP(ret_edhec, layout = c(2, 7))
```

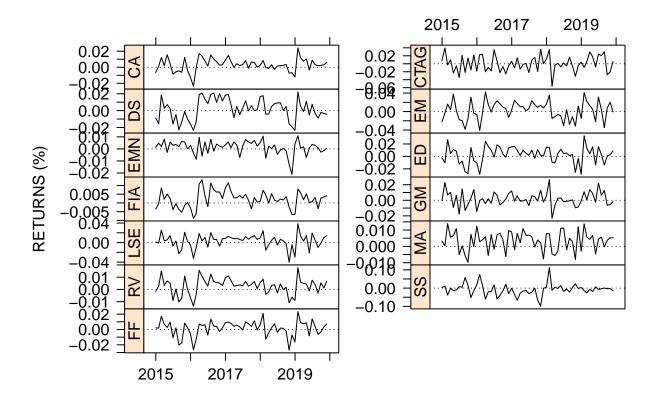

Fig 2.1

The CRSP data set is the daily log returns of 30 small cap stocks from 1993-01 to 2015-12 from the Center for Research in Security Prices (CRSP). We use this larger and more frequent data set to show more meaningful and interesting results in Section 9. We don't want to use the large data set everywhere to slow down the code or distract the main point.

```

In the following part, we only show the time series of monthly returns of 10 CRSP stocks in the last five years, but you can use this code to check the time series performance of all stocks in any frequency and any time period.

```
# generate monthly return in last 5 years
ep <- endpoints(ret_CRSP, on= "months", k=1)
sum1 <- function(x){apply(x, 2, sum)}
retM_CRSP <- period.apply(ret_CRSP, INDEX = ep, FUN = sum1)
retM_CRSP_5 <- tail(retM_CRSP, 60)

# time series plot of 10 stocks
tsPlotMP(retM_CRSP_5[, 1:10])</pre>
```

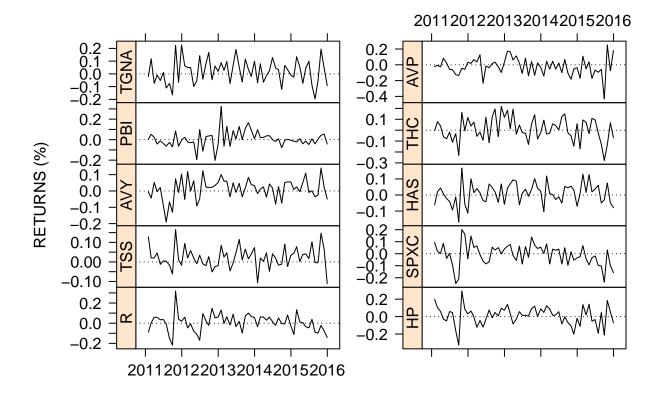

Fig 2.2

2.4 Optimization Problems

All optimization problems treated will use linear constraints unless stated otherwise. There will be one equality constraint, i.e., the full-investment constraint, and one or more inequality constraints such as the long-only and box constraints. More comprehensive constraint types can be found in the vignette Ross (2018) *Introduction to PortfolioAnalytics*. This vignette will be organized by objective type and provide some visual examples.

3 Maximizing Mean Return

The objective to maximize mean return is a linear problem of the form:

$$\max_{w} \quad \hat{\boldsymbol{\mu}}' \boldsymbol{w}$$

$$s.t. \quad A\boldsymbol{w} \ge b$$

$$B\boldsymbol{w} = c$$

Where $\hat{\mu}$ is the estimated asset returns mean vector and w is the vector of portfolio weights.

3.1 Portfolio Object

The first step in setting up a model is to create the portfolio object. Then add constraints and a return objective.

```
## *************
## PortfolioAnalytics Portfolio Specification
## **************
##
## Call:
## portfolio.spec(assets = fund_edhec)
##
## Number of assets: 13
## Asset Names
            "CTAG" "DS"
                         "EM"
                               "EMN" "ED"
## [1] "CA"
                                           "FIA"
                                                 "GM"
                                                       "LSE"
                                                             "MA"
## More than 10 assets, only printing the first 10
## Constraints
## Enabled constraint types
      - full investment
##
##
      - box
##
## Objectives:
## Enabled objective names
      - mean
```

3.2 Optimization

The next step is to run the optimization. Note that optimize_method=c("CVXR", {CVXRsolver}) should be specified in the function optimize.portfolio to use CVXR solvers for the optimization, or use the default solver by giving optimize_method="CVXR". For maximizing mean return problem, which is a linear programming, the default solver is OSQP.

```
## ***********
##
## Call:
## optimize.portfolio(R = ret_edhec, portfolio = pspec_maxret, optimize_method = "CVXR",
##
      trace = TRUE)
##
## Optimal Weights:
##
    CA CTAG DS
                 EM EMN
                         ED FIA
                                  GM LSE
                                           MA
                                               RV
                                                   SS
                                                        FF
##
## Objective Measures:
##
      mean
## 0.002728
opt_maxret$solver
## [1] "OSQP"
# Run the optimization with specific solver
opt_maxret_glpk <- optimize.portfolio(R=ret_edhec, portfolio=pspec_maxret,</pre>
                            optimize_method=c("CVXR", "GLPK"), trace=TRUE)
opt_maxret_glpk$solver
## [1] "GLPK"
```

3.3 Backtesting

An out of sample backtest is run with optimize.portfolio.rebalancing. In this example, an initial training period of 36 months is used and the portfolio is rebalanced quarterly.

The call to optimize.portfolio.rebalancing returns the bt_maxret object which is a list containing the optimal weights and objective measure at each rebalance period.

```
class(bt_maxret)

## [1] "optimize.portfolio.rebalancing"

names(bt_maxret)

## [1] "portfolio" "R" "call" "elapsed_time"

## [5] "opt_rebalancing"
```

4 Minimizing Variance

The objective to minimize variance is a quadratic problem of the form:

$$\min_{\boldsymbol{w}} \quad \boldsymbol{w}' \Sigma \boldsymbol{w}$$

subject to only the full-investment constraint, where Σ is the estimated covariance matrix of asset returns and \boldsymbol{w} is the set of weights. It is a quadratic problem.

4.1 Global Minimum Variance Portfolio

4.1.1 Portfolio Object

In this example, the only constraint specified is the full investment constraint, therefore the optimization problem is solving for the global minimum variance portfolio.

```
# Create portfolio object
pspec_gmv <- portfolio.spec(assets=fund_edhec)
# Add full-investment constraint
pspec_gmv <- add.constraint(pspec_gmv, type="full_investment")
# Add objective of minimizing variance
pspec_gmv <- add.objective(portfolio = pspec_gmv, type = "risk", name = "var")</pre>
```

4.1.2 Optimization

StdDev

0.002011

##

```
opt_gmv <- optimize.portfolio(ret_edhec, pspec_gmv, optimize_method = "CVXR")</pre>
opt_gmv
## **********
## PortfolioAnalytics Optimization

As this example illustrates, a global minimum variance portfolio can have short positions.

4.2 Linearly Constrained Minimum Variance Portfolio

Various linear inequality constraint, such as box constraints, group constraints and a target mean return constraint, can be used with GMV portfolio construction. Here we demonstrate the case of linearly constrained minimum variance portfolio.

```
# portfolio object
pspec_mv <- add.constraint(pspec_gmv, type = "long_only")</pre>
pspec_mv <- add.constraint(pspec_mv, type = "group",</pre>
                           groups=list(groupA=1,
                                      groupB=c(2:12),
                                      groupC=13),
                           group min=c(0, 0.05, 0.05),
                           group_max=c(0.4, 0.8, 0.5))
pspec_mv <- add.constraint(pspec_mv, type = "return", return_target=0.003)</pre>
pspec_mv

5 Maximizing Quadratic Utility

Next we demonstrate the classical quadratic utility form of Markowitz's mean-variance model, where the quadratic utility function is $QU(\boldsymbol{w}) = \mu_p - \lambda \sigma_p^2 = \boldsymbol{\mu'w} - \lambda \boldsymbol{w'} \Sigma \boldsymbol{w}$:

$$\max_{w} \quad \hat{\boldsymbol{\mu}}' \boldsymbol{w} - \lambda \boldsymbol{w}' \Sigma \boldsymbol{w}$$

$$s.t. \quad A\boldsymbol{w} \ge b$$

Where $\hat{\boldsymbol{\mu}}$ is the estimated mean asset returns, $0 \leq \lambda < \inf$ is the risk aversion parameter, Σ is the estimated covariance matrix of asset returns and \boldsymbol{w} is the set of weights. Quadratic utility maximizes return while penalizing variance. The risk aversion parameter λ controls how much portfolio variance is penalized, and when $\lambda = 0$ it becomes a maximum mean return problem of Section 3, and as $\lambda \to \inf$, it becomes the minimum variance problem of Section 4.

5.1 Portfolio Object

In this case the objectives of the portfolio should be both return and risk, and for this example we will use a risk aversion parameter λ to be 10 by setting risk_aversion = 10.

5.2 Optimization

The optimization result opt_mvo shows the call, optimal weights, and the objective measure. Objective measure contains quadratic utility, mean return and standard deviation.

```
opt_mvo <- optimize.portfolio(ret_edhec, pspec_mvo, optimize_method = "CVXR")
opt_mvo</pre>
```

```

6 Minimizing Expected Shortfall

Expected Shortfall(ES) is also called Conditional Value-at-Risk(CVaR) and Expected Tail Loss(ETL). The ES of a portfolio is

$$ES_{\gamma}(w) = -E(r_P|r_P \le q_{\gamma}(\boldsymbol{w}))$$

= $-E(\boldsymbol{w'r}|\boldsymbol{w'r} \le q_{\gamma}(\boldsymbol{w}))$

where r_P is a random return of a portfolio P, and r is the loss return which is negative, and q_{γ} is γ -quantile and γ is usually a "tail" probability such as 0.01, 0.05, in which case ES is a tail risk measure. But one could also choose $\gamma = 0.25$ or $\gamma = 0.5$, in which case ES is just a "downside" risk measure, and if $\gamma > 0.5$, the problem will take $1 - \gamma$ as the tail probability.

It was shown by Rockafellar and Uryasev (2000) that the optimal minimum ES portfolio is the result of the minimization:

$$\min_{\boldsymbol{w}} ES_{\gamma}(\boldsymbol{w}) = \min_{\boldsymbol{w},t} F_{\gamma}(\boldsymbol{w},t)$$

where

$$F_{\gamma}(oldsymbol{w},t) = -t + rac{1}{\gamma} \int [t - oldsymbol{w'r}]^+ \cdot f(oldsymbol{r}) doldsymbol{r}$$

by replacing q_{γ} with the free variable t, and with the discrete data the formula is:

$$\hat{F}_{\gamma}(\boldsymbol{w},t) = -t + \frac{1}{n \cdot \gamma} \sum_{i=1}^{n} [t - \boldsymbol{w'r_i}]^+$$

Hence, the minimization of ES is equivalent to solving a linear programming problem.

The ES objective is in the form of:

$$\min_{\boldsymbol{w},t} \quad -t + \gamma^{-1} E(t - \boldsymbol{w'r_i})^+$$

where $0 < \gamma < 1$ is the quantile value, and t is the value from which shortfalls are measured in the optimal solution. Many authors also use p or α as the quantile, e.g., in Rockafellar and Uryasev (2000) and other vignettes of PortfolioAnalytics, and use η as the risk measure variable, e.g., in Krokhmal (2007).

6.1 Portfolio Object

The default probability is $\gamma = 5\%$. Specific probability could be given by arguments.

7 Minimizing Expected Quadratic Shortfall

Expected Quadratic Shortfall(EQS) is also called Second-Moment Coherent Risk Measure(SMCR). The objective to minimize EQS is in the form of:

$$\min_{w,t} -t + \gamma^{-1} ||(t - w'r_i)^+||_2$$

where γ is the tail probability and $0 < \gamma < 1$, t is the value from which quadratic shortfalls are measured in the optimal solution. The default probability is $\gamma = 5\%$. Minimizing EQS could be incorporated into a

convex problem as a second-order cone constraints, and PortfolioAnalytics uses SCS in CVXR as the default solver for Second-Order Cone Optimization(SOCopt).

7.1 Portfolio Object

The default probability is $\gamma = 5\%$. Specified probability could be given by arguments.

7.2 Optimization

```
opt_eqs <- optimize.portfolio(ret_edhec, pspec_eqs, optimize_method = "CVXR")</pre>

8 Maximizing Mean Return Per Unit Risk

There are three basic types of risk measures: variance or standard deviation, ES and EQS. The problem of maximizing mean return per unit risk can be solved in a clever way by minimizing risk with a target return constraint, as is described below. For all three of these types of problems, both return and risk objectives should be used in PortfolioAnalytics. Then for each of these three optimization problems an appropriate argument needs to be given to the optimize.portfolio to specify the type of problem.

8.1 Maximum Sharpe Ratio Portfolios

The Sharpe Ratio of a random return r_P of a portfolio P is defined as:

$$\frac{E(r_P) - r_f}{\sqrt{Var(r_P)}}$$

The problem of maximizing the Sharpe Ratio can be formulated as a quadratic problem with a budget normalization constraint. It is shown in Cornuéjols, G., Peña, J., & Tütüncü, R. (2018), that this optimization problem is:

minimize
$$w'\Sigma w$$

s.t. $(\hat{\mu} - r_f \mathbf{1})^T w = 1$
 $\mathbf{1}^T w = \kappa$
 $\kappa > 0$

which has a solution (w^*, κ^*) with $k^* \neq 0$, and the maximized Sharpe ratio given by $\tilde{w}^* = w^*/\kappa^*$.

When creating the portfolio, the argument maxSR = TRUE should be specified in the function optimize.portfolio to distinguish from the mean-variance optimization. NOTE: The default argument is maxSR = FALSE since the default action for dealing with both mean and var/StdDev objectives is to maximize quadratic utility.

```

8.2 Maximum ES ratio Portfolios

The ES ratio(ESratio), which is also called STARR in PortfolioAnalytics, is defined as:

$$\frac{E(r_P) - r_f}{ES_{\gamma}(r_P)}$$

Similar to maximizing Sharpe Ratio, the problem maximizing the ES ratio can be formulated as a minimizing ES problem with a budget normalization constraint.

When creating the portfolio, both return and ES objectives should be given. The default $\gamma=0.05$, and it can be specified by arguments. When solving the problem, the default argument ESratio=TRUE in the function optimize.portfolio specifies the problem type. We note that this argument is equivalent to maxSTARR=TRUE, which is used in other vignettes. If one of these two arguments is specified as FALSE, the action will be to minimize ES ignoring the return objective.

8.3 Maximum EQS ratio Portfolios

The EQS ratio of a random return r_P of a portfolio P is defined as:

$$\frac{E(r_P) - r_f}{EQS_{\gamma}(r_P)}$$

Similar to maximizing Sharpe Ratio, the problem maximizing EQS ratio could be formulated as a minimizing EQS problem with a budget normalization constraint.

When creating the portfolio, both return and EQS objectives should be given. The argument EQSratio= is used to specify the problem type and the default value is EQSratio=TRUE. If EQSratio=FALSE, the action will be to minimize EQS ignoring the return objective. The default $\gamma = 0.05$, and it can be specified by arguments.

9 Performance of Portfolios

CVXR solvers provide the Second-Order Cone Optimization (SOCopt) capability required to minimize EQS problem, and managing EQS is of great significance for building portfolios.

In this section, we use the CRSP data set to generate GMV, ES and EQS portfolios and show their performance by plotting cumulative returns and efficient frontiers. In this process, we would like to show the value of EQS in managing portfolios.

9.1 Backtesting with GMV, GMES, GMEQS portfolios

In this example, we use daily return of all the CRSP 30 small cap stocks to generate a comparative backtesting among Global Minimum Variance, Global Minimum ES and Global Minimum EQS portfolio. The strategy is to rebalance the portfolio at the end of each month with a rolling window of 500 days, and the performance of backtesting could be shown as a plot of cumulative returns and a plot of drawdown.

```
## Generate GMV, GMES and GMEQS portfolios
pspec_sc <- portfolio.spec(assets=fund_CRSP)</pre>
pspec_sc <- add.constraint(pspec_sc, type="full_investment")</pre>
pspec_sc <- add.constraint(pspec_sc, type="long_only")</pre>
pspec GMV <- add.objective(pspec sc, type="risk", name="var")</pre>
pspec_GMES <- add.objective(pspec_sc, type="risk", name="ES")</pre>
pspec_GMEQS <- add.objective(pspec_sc, type="risk", name="EQS")</pre>
## Optimize Portfolio at Monthly Rebalancing and 500-Day Training
bt.GMV <- optimize.portfolio.rebalancing(ret_CRSP, pspec_GMV,</pre>
                                              optimize method="CVXR",
                                              rebalance_on="months",
                                              training_period=30,
                                              rolling_window=500)
bt.ES <- optimize.portfolio.rebalancing(ret_CRSP, pspec_GMES,
                                              optimize method="CVXR",
                                              rebalance on="months",
                                              training_period=30,
                                              rolling window=500)
bt.EQS <- optimize.portfolio.rebalancing(ret_CRSP, pspec_GMEQS,</pre>
                                              optimize_method="CVXR",
                                              rebalance on="months",
                                              training_period=30,

9.2 Backtesting with SR, ESratio, EQSratio portfolios

In this example, we use daily return of all the CRSP 30 small cap stocks to generate a comparative backtesting among Maximum Sharpe Ratio, Maximum ES Ratio and Maximum EQS Ratio portfolio. The strategy is to rebalance the portfolio at the end of each month with a rolling window of 500 days, and the performance of backtesting could be shown as a plot of cumulative returns and a plot of drawdown.

```
rolling_window=500)
bt.EQSr <- optimize.portfolio.rebalancing(ret_CRSP, pspec_EQSr,
                                             optimize_method="CVXR",
                                             rebalance on="months",
                                             training_period=30,
                                             rolling window=500)
## Extract time series of portfolio weights
wts.Sr = extractWeights(bt.Sr)
wts.Sr <- wts.Sr[complete.cases(wts.Sr),]</pre>
wts.ESr = extractWeights(bt.ESr)
wts.ESr <- wts.ESr[complete.cases(wts.ESr),]</pre>
wts.EQSr = extractWeights(bt.EQSr)
wts.EQSr <- wts.EQSr[complete.cases(wts.EQSr),]</pre>
## Compute cumulative returns of three portfolios
Sr = Return.rebalancing(retM_CRSP, wts.Sr)
ESr = Return.rebalancing(retM_CRSP, wts.ESr)
EQSr = Return.rebalancing(retM_CRSP, wts.EQSr)
# Combine Sr, ESr and EQSr portfolio cumulative returns
ret.comb <- na.omit(merge(Sr, ESr, EQSr, all=F))</pre>

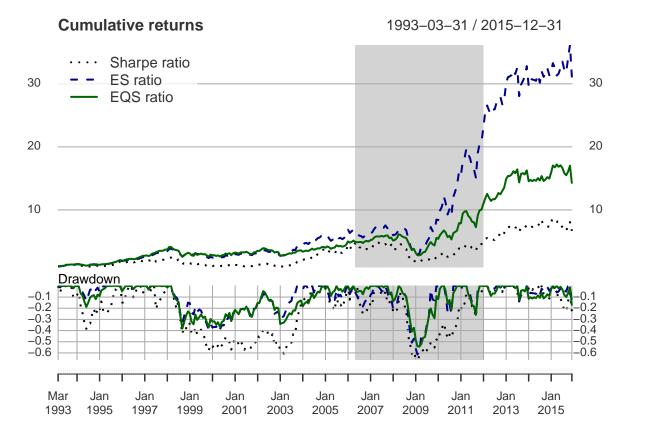

Fig 9.2

9.3 Efficient Frontier

We generate efficient frontiers with mean-StdDev, mean-ES and mean-EQS portfolios by using 30 small cap stocks from CRSP data set. Considering that the data may show different properties over a long period of

time, we only use the monthly return in the last 5 years to generate efficient frontiers, that is from 2011-01 to 2015-12 and defined in Section 2.3 as retM_CRSP_5. We can use create.EfficientFrontier to calculate the mean value and risk value for the frontier, then use chart.EfficientFrontier to draw the frontier.

9.3.1 Mean-StdDev Efficient Frontier

```
# mean-var efficient frontier
meanvar.ef <- create.EfficientFrontier(R=retM_CRSP_5, portfolio=pspec_sc, type="mean-StdDev")

Note that we have introduced the method of finding the maximum Sharpe ratio portfolio in Section 8.1, which
may be different from the "maximum" Sharpe ratio calculated from the discrete efficient frontier value. We
can identify the maximum Sharpe ratio portfolio in blue point on the mean-StdDev efficient frontier.

Mean-StdDev Efficient Frontier

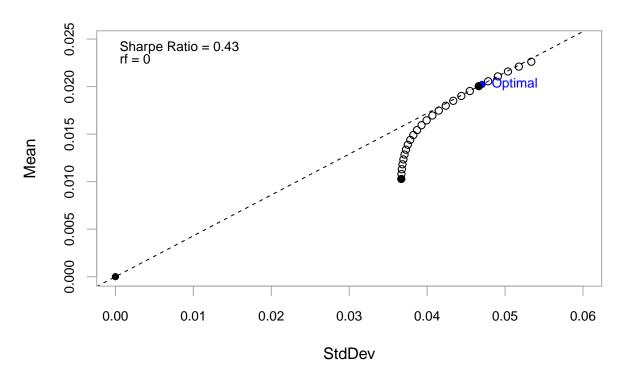

Fig 9.4

The theoretical maximum Sharpe ratio portfolio is very close to the result generated by the efficient frontier, and the Sharpe ratio value is almost the same but the mean and StdDev value are slightly different. That is because efficient frontier uses a discrete mean value.

With different constraint types, we can create mean-StdDev efficient frontiers for multiple portfolios and overlay the plots.

```
pspec_sc_init <- portfolio.spec(assets=fund_CRSP)
pspec_sc_init <- add.constraint(pspec_sc_init, type="full_investment")</pre>
```

```
# Portfolio with long-only constraints
pspec_sc_lo <- add.constraint(portfolio=pspec_sc_init, type="long_only")</pre>
# Portfolio with long-only box constraints
pspec_sc_lobox <- add.constraint(portfolio=pspec_sc_init, type="box", min=0.02, max=0.1)
# Portfolio with long-short box constraints
pspec_sc_lsbox <- add.constraint(portfolio=pspec_sc_init, type="box", min=-0.1, max=0.1)
# Combine the portfolios into a list
portf_list <- combine.portfolios(list(pspec_sc_lo, pspec_sc_lobox, pspec_sc_lsbox))</pre>
# Plot the efficient frontier overlay of the portfolios with varying constraints
legend_labels <- c("Long Only", "Long Only Box", "Long Short Box")</pre>
chart.EfficientFrontierOverlay(R=retM_CRSP_5, portfolio_list=portf_list,
                               type="mean-StdDev", match.col="StdDev",
                               legend.loc="topleft", chart.assets = FALSE,
                               legend.labels=legend_labels, cex.legend=1,
                               labels.assets=FALSE, lwd = c(3,3,3),
                               col = c("black", "dark red", "dark green"),
                               main="Overlay Mean-StdDev Efficient Frontiers",
                               xlim = c(0.03, 0.06), ylim = c(0.005, 0.025))
```

Overlay Mean-StdDev Efficient Frontiers

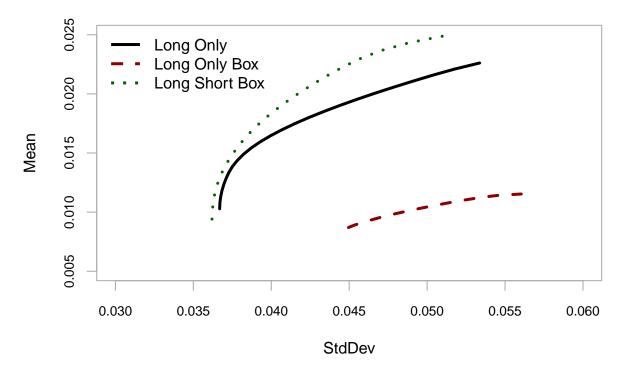

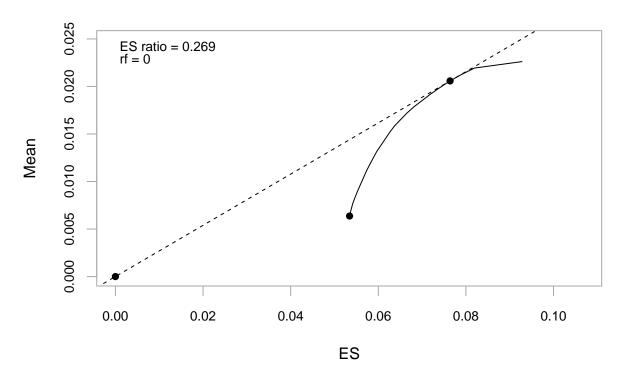

Fig 9.5

The plot clearly show that the portfolio under the long-short box constraints has the best performance.

9.3.2 Mean-ES Efficient Frontier

Generate the mean-ES efficient frontier:

Mean-ES Efficient Frontier

 $\mathrm{Fig}\ 9.6$

Generate multiple mean-ES efficient frontiers and overlay the plots.

Overlay Mean-ES Efficient Frontiers

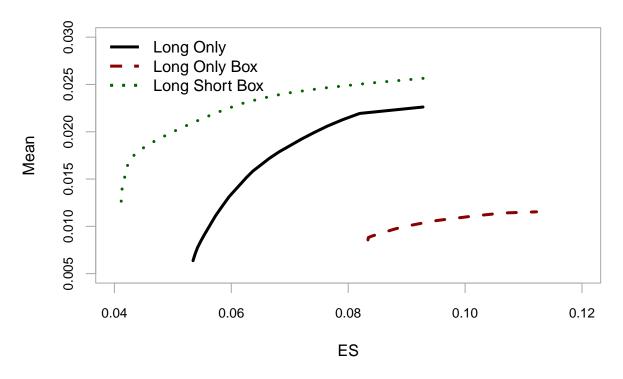

Fig 9.7

Instead of generating efficient frontiers with different constraint types, we can also generate mean-ES efficient frontiers with different tail probability γ .

```
# Create long-only ES portfolios with different tail probabilities
ES_05 <- add.objective(portfolio=pspec_sc_lo, type="risk", name="ES",
                          arguments=list(p=0.05))
ES_10 <- add.objective(portfolio=pspec_sc_lo, type="risk", name="ES",
                          arguments=list(p=0.1))
ES_15 <- add.objective(portfolio=pspec_sc_lo, type="risk", name="ES",
                      arguments=list(p=0.15))
# Combine the portfolios into a list
portf_ES_list <- combine.portfolios(list(ES_05, ES_10, ES_15))</pre>
# Plot the efficient frontier overlay of the portfolios with varying tail probabilities
legend_ES_labels <- c("ES (p=0.05)", "ES (p=0.1)", "ES (p=0.15)")
chart.EfficientFrontierOverlay(R=retM_CRSP_5, portfolio_list=portf_ES_list,
                               type="mean-ES", match.col="ES",
                               legend.loc="topleft", chart.assets = FALSE,
                               legend.labels=legend_ES_labels, cex.legend=1,
                               labels.assets=FALSE, lwd = c(3,3,3),
```

```
col = c("black", "dark red", "dark green"),
main="Overlay Mean-ES Efficient Frontiers",
xlim = c(0.03, 0.1), ylim = c(0.005, 0.025))
```

Overlay Mean-ES Efficient Frontiers

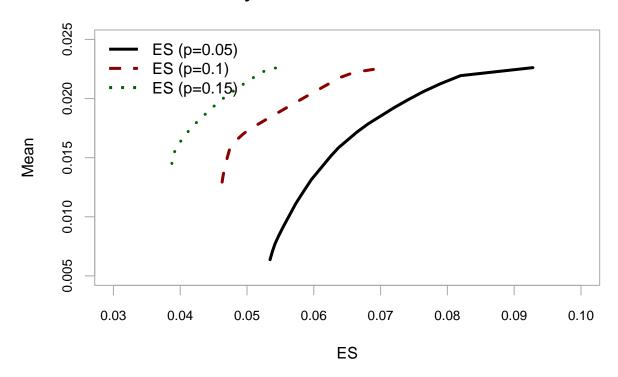

Fig 9.8

ES portfolio with a larger tail probability will have better performance.

9.3.3 Mean-EQS Efficient Frontier

Mean-EQS Efficient Frontier

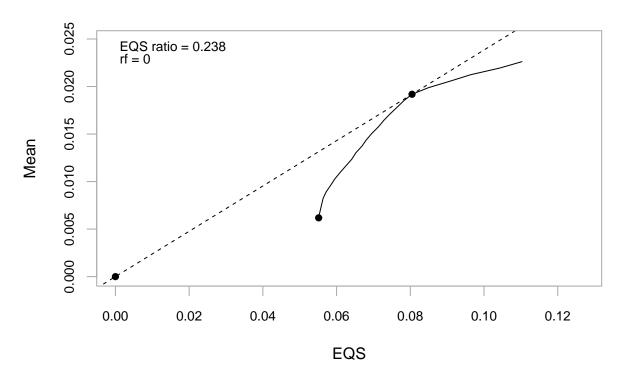

Fig 9.9

Mean-EQS efficient frontier is more like a piecewise function rather than a smooth curve.
